# GROUP CRYPTOGRAPHY AND DISCRETE LOGARITHMS

Enes KALECI

28/05/2025

## **Abstract**

This study investigates the basic uses of group theory in encryption and the importance of the discrete logarithm problem in cryptographic security. The first phase covers the ElGamal encryption algorithm, followed by the presentation of key strategies for solving the discrete logarithm problem: the baby-step giant-step method, the Pohlig-Hellman algorithm, and the index calculus method. Other mathematical tools, such as the Chinese Remainder Theorem, that aid in the acceleration of systems based on discrete logarithms, as well as cryptographic attacks like birthday attacks, are examined.

In phase two, the theoretical concepts were implemented as practical models within the SageMath software. The algorithms of interest were created and executed using SageMath in order to demonstrate how the operational heuristics could be inspected to showcase the power of computer algebra systems in cryptographic tasks.

## **Acknowledgement**

I would like to thank my Instructor, Doga Can Sertbas, for the guidance and support he provided throughout this study.

# 1 The ElGamal Encryption Scheme

## ElGamal Encryption Protocol:

- **Set-up:** Choose a finite cyclic group  $G = \langle g \rangle$  with  $d$  elements. Let  $g$  be a generator. These are made public.
- **Key Generation:**
  - Private key:  $b \in \mathbb{Z}_d$
  - Public key:  $B = g^b \in G$
- **Encryption:**
  - Input: plaintext  $x \in G$
  - Choose random  $a \in \mathbb{Z}_d$
  - Compute  $A = g^a$ ,  $k = B^a$ ,  $y = x \cdot k$
  - Output: ciphertext  $(y, A)$
- **Decryption:**
  - Input: ciphertext  $(y, A)$
  - Compute  $k = A^b$ , then  $x = y \cdot k^{-1}$

Below the code of the protocol is written using sagemath and is mentioned below.

## Python / SageMath Implementation:

```
1 p = random_prime(2^11, 2^12)
2 G = GF(p)
3 g = G.primitive_element()
4 print(f"Prime_number_(p):_{p}")
5 print(f"Generator_(g):_{g}")
6
7 # Key Generation
8 b = randint(0, p-1)
9 B = g^b
10 print(f"Private_Key_(b):_{b}")
11 print(f"Public_Key_(B):_{B}")
12
13 # Message input
14 x_input = input(f"Enter_a_number_in_GF({p})_(x):_")
15 x = G(int(x_input))
16
17 # Encryption Function
18 def encrypt(x, B, g, p):
19     a = randint(0, p-1)
20     A = g^a
21     k = B^a
22     y = x * k
23     return (y, A)
24
```

```

25 ciphertext = encrypt(x, B, g, p)
26 print(f"A:_{ciphertext[1]}")
27 print(f"y:_{ciphertext[0]}")
28 print(f"Ciphertext_{y,_A}:_{ciphertext}")
29
30 # Decryption Function
31 def decrypt(y, A, b, p):
32     k = A^b
33     k_inv = k^(-1)
34     print(f"Shared_secret_{k}:_{k}")
35     print(f"Inverse_of_k:_{k_inv}")
36     return y * k_inv
37
38 decrypted_x = decrypt(ciphertext[0], ciphertext[1], b, p)
39 print(f"Decrypted_Message:_{decrypted_x}")

```

## 2 Baby-step Giant-step Algorithm

**Algorithm 1.** Baby-step Giant-step for discrete logarithms

**Input:**

- A cyclic group  $G = \langle g \rangle$  with order  $d$
- Element  $x \in G$

**Output:**  $\log_g x \in \mathbb{Z}_d$

1. Set  $m = \lceil \sqrt{d} \rceil$
2. Compute and store:  $xg^j \bmod n$  for  $j = 0$  to  $m - 1$
3. Compute  $g^m$ , then  $g^{im} \bmod n$  for  $i = 1$  to  $m$
4. If a match is found, return  $a = im - j$

The code for the Baby-Step Giant-Step Algorithm was written using `sagemath` and gives the code.

**Python / SageMath Implementation:**

```
1 from math import ceil, sqrt
2 from math import gcd
3
4 def BSGS(g, x, n, order):
5     if gcd(g, n) != 1 or gcd(x, n) != 1:
6         print("ERROR: g and x must be coprime with n.")
7         return None
8
9     m = ceil(sqrt(order))
10    baby_steps = {}
11
12    for j in range(m):
13        val = (x * pow(g, j, n)) % n
14        baby_steps[val] = j
15        print(f"Baby_{j}={j}: {x} * {g}^{j} mod {n}")
16
17    g_m = pow(g, m, n)
18    for i in range(1, m + 1):
19        y = pow(g_m, i, n)
20        print(f"Giant_{i}={i}: {g}^{i*m} mod {n}")
21        if y in baby_steps:
22            j = baby_steps[y]
23            result = (i * m - j) % order
24            print(f"Result: k={i*m - j} mod {order} = {result}")
25            return result
26
27    print("No solution found.")
28    return None
29
30
31 n = 25
32 g = 2
33 x = 17
```

```
34 order = 20
35 k = BSGS(g, x, n, order)
```

Listing 2: Baby-step Giant-step Implementation

### 3 Birthday Algorithm for Discrete Logarithm

#### Algorithm 2. Birthday Algorithm for Discrete Logarithm

**Input:** A cyclic group  $G = \langle g \rangle$  with  $d$  elements, and a group element  $x \in G$ .

**Output:**  $\log_g x \in \mathbb{Z}_d$ .

1. Initialize sets  $X \leftarrow \emptyset, Y \leftarrow \emptyset$ .
2. Repeat until a collision occurs:
  - Randomly choose  $b \in \{0, 1\}$ , and  $i \in \{0, \dots, d - 1\}$
  - If  $b = 0$ : compute  $xg^i$ , store in  $X$
  - If  $b = 1$ : compute  $g^i$ , store in  $Y$
3. If a collision  $xg^i = g^j$  is found: return  $j - i \pmod d$

The code for the Birthday Algorithm was written using sagemath and gives the code.

#### Python / SageMath Implementation:

```
1
2 def birthday_algorithm(g, x, p):
3     d = totient(p) # Euler's totient function
4     X, Y = {}, {} # Hash tables for collision detection
5
6     while True:
7         b = randint(0, 1)
8         i = randint(0, d - 1)
9
10        if b == 0:
11            value = (x * pow(g, i, p)) % p
12            if value in Y:
13                return (Y[value] - i) % d
14            X[value] = i
15        else:
16            value = pow(g, i, p)
17            if value in X:
18                return (i - X[value]) % d
19            Y[value] = i
20
21 # User input
22 p = int(input("Modular number p (prime): "))
23 G = GF(p)
24 g = G.primitive_element()
25 print(f"Primitive element over GF({p}): {g}")
26 x = int(input("Encrypted message x: "))
27
28 dlog = birthday_algorithm(g, x, p)
29 print(f"\nDiscrete logarithm in Z{p}*: {dlog}")
30 check = pow(int(g), dlog, p)
31 print(f"Verification: g^a mod p = {check}, x = {x} (should be equal)")
```

Listing 3: Birthday Algorithm Implementation

## 4 Chinese Remaindering for Discrete Logarithms

**Algorithm Description:** The Chinese remaindering method for discrete logarithms is used when the group order  $d$  can be factored into small prime components. The discrete logarithm problem is solved separately modulo each prime factor, and these smaller solutions are then combined using the Chinese Remainder Theorem to obtain the overall solution.

**Algorithm 3.** Chinese remaindering for discrete logarithms.

**Input:** A cyclic group  $G = \langle g \rangle$  of order  $d = \#G$ , and  $x \in G$ .

**Output:**  $a = \text{dlog}_g x$ .

1. Compute the prime power factorization of  $d$ .
2. For each  $i \leq r$ , do steps 3 and 4:
  - (a) Compute  $g_i = g^{d/q_i}$  and  $x_i = x^{d/q_i}$ , using the Repeated Squaring Algorithm
  - (b) Compute the discrete logarithm  $a_i = \text{dlog}_{g_i} x_i \in \mathbb{Z}_{q_i}$  in  $S_i = \langle g_i \rangle$ .
3. Combine these “small” discrete logarithms via the Chinese Remainder Algorithm to find the unique  $a \in \mathbb{Z}_d$  such that  $a = a_i$  in  $\mathbb{Z}_{q_i}$  for all  $i \leq r$ .

The code for the Chinese Remaindering Algorithm was written using sagemath and gives the code.

**Python / SageMath Implementation:**

```
1
2 def dlog(g, x, n, order):
3     if gcd(g, n) != 1 or gcd(x, n) != 1:
4         print("ERROR: g and x must be coprime with n!")

## 5 The Pohlig-Hellman Algorithm

**Algorithm Description:** This algorithm works for groups of order  $p^e$ .

**Algorithm 4.** Pohlig-Hellman Algorithm

**Input:** A cyclic group  $G = \langle g \rangle$  of order  $p^e$ , where  $p$  is a prime,  $e \geq 2$  is an integer, and  $x \in G$ .

**Output:**  $a = \text{dlog}_G(x)$ , the discrete logarithm of  $x$  in  $G$ .

1. Compute  $h = g^{p^{e-1}}$  and set  $y_{-1} = 1 \in G$ .
2. For  $i = 0$  to  $e - 1$ , do:
  - (a)  $x_i \leftarrow (x \cdot y_{i-1}^{-1})^{p^{e-i-1}}$
  - (b) Compute  $a_i \leftarrow \text{dlog}_h(x_i)$ .
  - (c) Update  $y_i \leftarrow y_{i-1} \cdot g^{-a_i p^i}$ .
3. Return  $a = a_{e-1}p^{e-1} + \dots + a_0$ .

The code for the Pohlig hellman Algorithm was written using sagemath and gives the code.

Listing 5: Pohlig-Hellman Algorithm Implementation

## 6 Discrete logarithm in a cyclic group

**Algorithm 5.** Discrete Logarithm in a Cyclic Group (Pohlig-Hellman General Case)

**Input:** A finite cyclic group  $G = \langle g \rangle$  of order  $d$ , and an element  $x \in G$ .

**Output:**  $a = \log_g x$ , the discrete logarithm of  $x$  in  $G$ .

1. Factor the group order  $d$  as  $d = p_1^{e_1} \cdots p_r^{e_r}$  with distinct primes  $p_i$  and positive integers  $e_i$ .
2. For  $i = 1$  to  $r$ , do:
  - (a) Let  $q_i = p_i^{e_i}$ , and compute  $g_i = g^{d/q_i}$ ,  $x_i = x^{d/q_i}$ . These lie in the subgroup  $\langle g_i \rangle$  of order  $q_i$ .
  - (b) Compute the discrete logarithm  $a_i = \log_{g_i}(x_i)$ :
    - Use the Pohlig-Hellman algorithm recursively if  $e_i > 1$ ,
    - Use Baby-step Giant-step Algorithm if  $e_i = 1$ .
3. Combine the results  $a_i \bmod q_i$  using the Chinese Remainder Theorem to find  $a \bmod d$ .

## 7 Index Calculus Algorithm

**Algorithm 6.** Index Calculus Algorithm for Discrete Logarithm

**Input:** A prime  $p$ , a generator  $g \in \mathbb{Z}_p^*$ , and an element  $x \in \mathbb{Z}_p^*$ .

**Output:**  $a = \log_g x \mod (p-1)$

### 1. Factor Base Selection:

- Choose a smoothness bound  $B$ , and let  $\mathcal{F} = \{p_1, \dots, p_h\}$  be the set of all prime numbers  $\leq B$ .

### 2. Relation Collection:

- Repeat until  $h + 20$   $B$ -smooth relations are collected:
  - (a) Randomly choose  $e \in \mathbb{Z}_{p-1}$ .
  - (b) Compute  $y = g^e \mod p$ .
  - (c) If  $y$  is  $B$ -smooth over  $\mathcal{F}$ , i.e.,

$$g^e \equiv p_1^{\alpha_1} \cdots p_h^{\alpha_h} \mod p,$$

then we get the linear equation:

$$e \equiv \alpha_1 \log_g p_1 + \cdots + \alpha_h \log_g p_h \mod (p-1).$$

### 3. Solve Linear System:

- Use the collected relations to form a system of linear equations.
- Solve this system modulo  $p-1$  to find  $\log_g p_1, \dots, \log_g p_h$ .

### 4. Compute $\log_g x$ :

- Repeat:
  - (a) Randomly choose  $e \in \mathbb{Z}_{p-1}$ .
  - (b) Compute  $y = x \cdot g^e \mod p$ .
  - (c) If  $y$  is  $B$ -smooth:

$$x \cdot g^e \equiv p_1^{\beta_1} \cdots p_h^{\beta_h} \mod p,$$

then:

$$\log_g x \equiv -e + \beta_1 \log_g p_1 + \cdots + \beta_h \log_g p_h \mod (p-1).$$

- Return  $\log_g x$ .
